LIGHTYEAR

MS81 Measured calibration and schema session baselines

Customer benefit

Measure whether comparator work actually improves coverage on the same source estate, and inventory the database facts needed before promising a customer a useful comparison.

Delivered behavior

The pinned iDempiere replay reproduces the original 1,078-pair report, then runs the parser extensions and the calibrated gate. Decided SQL units rise from 776 to 780 out of the same 111,293 in-scope units across both dialects. Unsupported units fall from 6,595 to 1,405. Parser work alone does not increase decisions; comparing a safe ordered prefix before a later mismatch supplies the four extra decisions. No old decision or divergence is lost.

The parser retains deferred constraint and ENABLE/NOVALIDATE semantics, supports Oracle grouped column drops and national-character declarations, and never converts those unresolved domains into equality by deleting their obligations. The original audit implementation and retained artifacts remain unchanged.

A schema/session baseline binds every input and records required columns and source-located DDL. It leaves catalog completeness, triggers, constraints, row policies, rewrite rules and session settings unknown until evidence is supplied. The static numeric DML subset can consume complete contracts; stale facts, unknown side effects and unsupported expressions remain unresolved. Entry facts expire at schema/session/unknown operations.

Evidence and limits

Measured counts and explanation, reproduction and context contract, and synthetic context fixtures.

The synthetic context test moves from zero to four decided units out of six, retaining a one-cent mismatch and an unknown-trigger case. It is not customer capture evidence. The iDempiere result still has 1,077 indeterminate pairs. No native execution, customer qualification, or application-equivalence claim.

Validation

Parser negative tests, complete-input/context binding checks, changed-value and unknown-context controls, full pinned source reproduction, and unchanged retained audit validation run in the calibration suites. CI replays the public pinned source and compares the complete published measurement.
